ACIT 4850 – Enterprise System Integration – Winter 2026

Lesson 9 – Artifact Management

For Lesson 9 you will be setting up an Artifact Management tool for storing the built JAR files from your Java pipeline. The Artifact Management tool is SonaType Nexus 3 which stores and versions artifacts for a variety of artifact types.

What is a Software Artifact?

A software artifact is a by-product produced during the software development process. It may consist of software source code, dependencies, binaries or resources.

Source Code Artifacts

Software Developers are most interested in source code artifacts. As we already know, these are stored in a Source Code Management (SCM) tool.

Dependencies and Binary Artifacts

Software Developers, DevOps Engineers and Operations Engineers are also concerned with dependencies (i.e., packages or libraries) and binary artifacts.

Dependences include Python packages, Java JAR files, Ruby Gems, and other software libraries that are mean to be re-used in other software applications.

Binary artifacts are typically executable software like EXE files, Java JAR or WAR files, Zip files, software installers or other formats that are meant to be installed or run as a software application.

Artifact Management

Please review the following on Artifact Management before the Lesson 9 class:
